### Variables and Environments

Principles of Programming Languages
CAS CS 320
Lecture 16

### Practice Problem

$$[(\lambda x. xy)/z](\lambda x. \lambda y. yz)$$

Perform the following substitution, avoiding variable capture.

$$[v/y]x = \begin{cases} v & x = y \\ x & \text{else} \end{cases}$$

$$[v/y](\lambda x \cdot e) = \begin{cases} \lambda x \cdot e & x = y \\ \lambda z \cdot [w/z][z/x]e & x \in FV(v), z \notin FV(e) \\ \lambda x \cdot [v/y]e & \text{else} \end{cases}$$

$$[v/y](e_1e_2) = ([v/y]e_1)([v/y]e_2)$$

Answer

 $[(\lambda x. xy)/z](\lambda x. \lambda y. yz)$ 

### Outline

Demo an <u>implementation</u> of the lambda calculus

Discuss the difference between <u>lexical</u> and <u>dynamic</u> scoping

Look at the semantics of <u>variable binding</u>, with examples using <u>environments</u>

Begin to look at how <u>closures</u> are used to implement lexical scoping with environments

## Learning Objectives

- Describe the difference between dynamic and lexical scoping
- Give a sequence of reductions given a toy language which implements dynamic scoping
- Give a semantic derivation in the lambda calculus with let-expressions

# Demo (The Lambda Calculus)

# Variables

### Two Major Concerns

- 1. Are variables *mutable*? Can we change their values? Are there restrictions to when we can change the value of a variable?
- 2. How are variables *scoped*? Dynamically or lexically? Does a binding define its own scope? Is it defined in a block?

#### OCaml variables are:

- » immutable
- » binding defined
- » lexically scoped

### Mutability

```
let x = 0
let f () =
  let x = 1 in
  ()
print_int x

Immutable (OCaml)
```

```
x = 0
def f():
    global x
    x = 1
print(x)

Mutable (Python)
```

Definition. (informal) A variable is mutable if we are allowed to change its value after it has been declared.

#### We think of variables as:

- » names if they're immutable
- » (abstract) memory locations when they're immutable

### Scope

**Definition.** (Informal) The scope of a variable binding is when and where a variable can be accessed

Scoping rules describe how the scope of bindings works in a program.

#### There are two standard paradigms:

- » dynamic scoping
- » lexical scoping (static scoping)

Warning. Scope is one of the most unclear terms in computer science, we might be talking about:

- » the scope of a variable
- » the scope of a binding
- » the scope of a function
- » scopes in general (like global scope)
- "this variables is not in scope..."

### Dynamic Scoping

```
f() { x=23; g; }
g() { y=$x; }
f
echo $y
Bash
```

Dynamic scoping refers to when bindings are determined at runtime based on computational context

This is a *temporal view*, i.e., what a computation done beforehand which affected the value of a variable

### Lexical Scoping

```
x = 0
def f():
   x = 1
    return x
```

**Python** 

```
let x = 0
                  let f () =
                   let x = 1 in
                    X
|assert(f() == 1)| | let _ = assert (f () = 1)|
assert(x == 0) let_a = assert(x = 0)
                           OCaml
```

Lexical (static) scoping refers to the use of textual delimiters to define the scope of a binding

There are two common ways lexical scope is determined:

- » The binding defines it's own scope (let-bindings)
- » A block defines the scope of a variable (python functions)

## Environments

# High-Level

$$\{x \mapsto v , y \mapsto w , z \mapsto f\}$$

An *environment* is a data structure which maintains mappings of variables to values

Terminology. We call the individual mappings of variables to values variable bindings.

Usually it's implemented as an association list or a Map in OCaml. We have a special data structure called **env** for implementing environments.

The idea. We will evaluate expressions relative to an environment

### Operations

Math OCaml

& env

 $\mathscr{E}[x \mapsto v]$  add x v env

 $\mathscr{E}(x)$  find\_opt x env

 $\mathscr{E}(x) = \bot$  find\_opt x env = None

Most important operations on environments are the same that are useful for any dictionary-like data structure

Important: Adding mappings shadows existing mappings:

$$\mathscr{E}[x \mapsto v][x \mapsto w] = \mathscr{E}[x \mapsto w]$$

# Dynamic Scoping

## Toy Language (Syntax)

This is a small grammar for a language with, numbers, subroutines, and variable assignments

It's like a tiny fragment of Bash

### Toy Language (Semantics)

(func)

```
\langle \mathscr{E}, f() \{ P \}; Q \rangle \longrightarrow \langle \mathscr{E}[f \mapsto P], Q \rangle
```

$$\mathcal{E}(f) = P \in \mathbb{F}$$

$$\langle \mathcal{E}, f; Q \rangle \longrightarrow \langle \mathcal{E}, P Q \rangle$$
(call)

$$\mathcal{E}(y) = n \in \mathbb{Z}$$

$$\langle E, x = \$y; Q \rangle \longrightarrow \langle \mathscr{E}[x \mapsto n], Q \rangle$$

```
\langle E, x = n; Q \rangle \longrightarrow \langle \mathscr{E}[x \mapsto n], Q \rangle
```

**Note.** The environment contains both functions  $(\mathbb{F})$  and numbers  $(\mathbb{Z})$ 

# Toy Language (Example)

```
f() { x=23; g; }; g() { y=$x; }; f;
```

### The Takeaway

Defining and implementing dynamic scoping is very easy

It's like maintaining only a global scope

But it's behavior is harder to track, and arguably more error prone, you have to *remember* if there is some computation which will put a variable into scope.

Most modern programming languages implement lexical scoping

# Lexical Scoping

### Didn't we do this?

let x = v in ...

We've already implemented lexical scoping using the substitution model (mini-project 1)

Why do it again?

Answer. The substitution model is inefficient

Each substitution has to "crawl" through the entire remainder of the program

### The Environment Model (High-Level)

$$\langle \mathcal{E}, e \rangle \Downarrow v$$

Rather than *eagerly* substituting variables, we'll keep track of their values in an environment

We'll then evaluate *relative* to the environment, *lazily* filling in variable values along the way

Now the **configurations** in our semantics have nonempty state

(This might feel a bit more natural than substitution from the perspective of imperative languages)

### Lambda Calculus<sup>+</sup> (Syntax)

This is a grammar for the lambda calculus with let-expressions and numbers

Challenge Problem. Rewrite this grammar so that it is not ambiguous

### Lambda Calculus<sup>+</sup> (Semantics)

$$\langle \mathcal{E}, \lambda x.e \rangle \Downarrow \lambda x.e \qquad \langle \mathcal{E}, n \rangle \Downarrow n$$

$$\langle \mathcal{E}, x \rangle \Downarrow \mathcal{E}(x)$$

$$\langle \mathcal{E}, e_1 \rangle \Downarrow \lambda x. e \qquad \langle \mathcal{E}, e_2 \rangle \Downarrow v_2 \qquad \langle \mathcal{E}[x \mapsto v_2], e \rangle \Downarrow v$$

$$\langle \mathcal{E}, e_1 e_2 \rangle \Downarrow v$$

$$\langle \mathscr{E}, e_1 \rangle \Downarrow v_1 \qquad \langle \mathscr{E}[x \mapsto v_1], e_2 \rangle \Downarrow v_2$$
$$\langle \mathscr{E}, \text{let } x = e_1 \text{ in } e_2 \rangle \Downarrow v_2$$

Important. These rules are incorrect!

# What went wrong?

let 
$$x = 0$$
 in let  $f = \lambda y \cdot x$  in let  $f = 0$  in  $f = 0$ 

What is the value of this expression?

We'll see on the next slide that we accidentally implemented dynamic scoping

### The Derivation

```
\langle \emptyset \rangle, let x = 0 in let f = \lambda y \cdot x in let x = 1 in f(0) \rangle \downarrow 1
```

## Closures (Looking Ahead)

let 
$$x = 0$$
 in let  $f = \lambda y \cdot x$  in let  $f = 0$  in  $f = 0$ 

What do we do about this?

The problem was that f saw a different value of x than what it was when f 0 was evaluated

So functions will need to remember the environments they were defined in

### Summary

To deal with variables in an imperative setting, we need environments

To deal with variables in a function setting, we don't *need* environments, but they will make our implementation more efficient

Dynamic scoping says a variable binding is determined by the computational context whereas <u>lexical</u> scoping says its determine by its lexical (textual) context
